1. Purpose and Scope

This standard establishes a test procedure for evaluating the performance of air cleaning devices as a function of particle size. This document is applicable on testing for spotchecking real-time cleanliness during operation, root out contamination and creating standardized testing routine for long-term monitoring and data logging.

2. Responsibility

- 1. The expert of IPQC unit is responsible for preparing URS.
- 2. The manager and head of the QC are responsible for the approval of this document.
- 3. The quality assurance manager and technical officer are responsible for approving this document.

3. Overview

Optical particle counters (OPC) or spectrometers employ a small sensing volume, either by a focused incandescent lamp or by a laser source. In such instruments it is important to avoid coincidence errors resulting from more than one particle in the sensing volume. The instrument manufacturer specifies the maximum number concentration which can be handled. Generally, commercial instruments handle concentrations of up to ~10⁶ particles/litre. Beyond this concentration limit, sample dilution is usually used, which decreases the accuracy of the determination of the concentration. The range of particle diameter that single-particle instruments are capable of handling is ~0.1 µm. Optical particle counters have found wide use, first in cleanroom monitoring and more recently in community air pollution and industrial hygiene studies. A number of laboratory instruments employing single-particle scattering have been constructed. A critical review of such instruments is given by Chigier and Stewart.

Based on previous light scattering experiments, the development of <u>airborne particle</u> counters and sizers started in the middle of the twentieth century and accelerated in the 1960s after the invention of lasers.

The particle size distribution in single-particle counters is determined by comparing the detected <u>pulse heights</u> of the optical signals that correspond to the single particle flow through a small illuminated zone with a standard <u>calibration curve</u>, obtained from a set of uniform particles of known diameter. For determination of the concentration, the flow rate (the volume to be tested) is also measured simultaneously. The different light detection geometries applied in different particle counters yield a wide range of instrument designs and constructions. As the dependence of the scattered intensity on the <u>refractive index</u> of the particles is less pronounced around 90° of scattering angle, in most airborne particle counters perpendicular scattering geometry is implemented.

4. Operational Requirements

4.1 Function specification

Size Channels

0.3 μm, 0.5 μm, 1.0 μm,

3.0 μm, 5.0 μm, 10.0 μm

Zero Count

1 count or less in 5 minutes

Coincidence Loss

Less than 5% at 400000

particles/ft3

Flow Rate

1.0 CFM

Counting Efficiency

50 % for 0.3 µm

Light Source

Long Life Laser™ diode

with 10-year Mean Time

to Failure (MTTF)

Count display

LCD

Maximum Count

9999999 display

Pump Type

Air vacuum, rated for

continuous use

Sample /Hold Times

1 second to 24 hours

Count Alarm

1 to 9999999 counts

Count Cycles

Up to 100 while in

automatic mode

Location label

0 to 999, appears on

printout

Data Storage

5,000 samples, scrollable

on Historical Data review

screen

Battery

Rechargable Li

Operating Time (Battery)

up to 6 hours

Battery Recharge Time

7 hours minimum

Communication

RS-232, RS-485, 802.11

b/g Wireless, 802.3

Ethernet, USB Client,

USB Host

Weight

Max 7.0 Kg

6.6 Procedural Constraints

- Since the handheld particle counter is small, it does not force airflow. Thus, due to the lower airflow, it can take longer than other particle counter options to produce reading.
- A handheld particle counter is designed for spot checks, so it does not integrate well into a real time system.

7. Lifecycle

7.1 Development

.N.A

7.2 Testing

- Verify that all aspects of the cleanroom system which contribute to its operational integrity (air handling, filtration systems, walls, ceilings, floors, etc.) are complete and functioning. The following primary tests shall be completed prior to performing the cleanliness classification tests:
- Airflow test
- Filter leak test
- Room pressurization test
- The Cleanroom has been purged for at least 12 hours before testing commences.
- > The rooms are divided into test grids as per minimum sampling locations requirement by ISO 14644-1:2015.
- ➤ The counter's sample rate is set to 1 m³/min and the sampling time set to 1 minute or as required.
- A minimum of 1 sample is taken at each grid, at a height of 1 meter above the floor.
- When an obstruction is encountered, the sample is to be taken at 300 mm above the obstruction.

7.3 Delivery/ Documentation

The manufacturer must comply with good documentation practice and deliver the necessary documentation to prove that the facility, system and equipment is constructed according to GMP

guidelines and in line with our URS. Thus, it must be documented that the materials used are compliant with GMP guidelines and the appropriate validation tests have been performed. Checklists should be used to validate that all parts of construction, equipment and systems are in concordance with GMP guidelines. These should include, but not be limited to: the material used, quality specification, certificates, test methods/protocols, responsible test person, number of tests performed, test results, transfer plans and reports, IQ, OQ, PQ, Certificate of Analyses (CoA)/Compliance (CoC), validation and documentation

7.4 Support and training

Training course should be performed by manufacturer on the site.
